Summary

Objectives: To summarise the state of the art during the year 2018 in consumer health informatics and education, with a special emphasis on the special topic of the International Medical Informatics Association (IMIA) Yearbook for 2019: "Artificial intelligence in health: new opportunities, challenges, and practical implications".

Methods: We conducted a systematic search of articles published in PubMed using a predefined set of queries that identified 99 potential articles for review. These articles were screened according to topic relevance and 14 were selected for consideration as best paper candidates. The 14 papers were then presented to a panel of international experts for full paper review and scoring. Three papers that received the highest score were discussed in a consensus meeting and were agreed upon as best papers on artificial intelligence in health for patients and consumers in the year 2018.

Results: Only a small number of 2018 papers reported Artificial Intelligence (AI) research for patients and consumers. No studies were found on AI applications designed specifically for patients or consumers, nor were there studies that elicited patient and consumer input on AI. Currently, the most common use of AI for patients and consumers lies in secondary analysis of social media data (e.g., online discussion forums). In particular, the three best papers shared a common methodology of using data-driven algorithms (such as text mining, topic modelling, Latent Dirichlet allocation modelling), combined with insight-led approaches (e.g., visualisation, qualitative analysis and manual review), to uncover patient and consumer experiences of health and illness in online communities.

Conclusions: While discussion remains active on how AI could 'revolutionise' healthcare delivery, there is a lack of direction and evidence on how AI could actually benefit patients and consumers. Perhaps instead of primarily focusing on data

and algorithms, researchers should engage with patients and consumers early in the AI research agenda to ensure we are indeed asking the right questions, and that important use cases and critical contexts are identified together with patients and consumers. Without a clear understanding on why patients and consumers need AI in the first place, or how AI could support individuals with their healthcare needs, it is difficult to imagine the kinds of AI applications that would have meaningful and sustainable impact on individual daily lives.

Keywords

Artificial intelligence, consumer informatics, patient, participatory health, machine learning, social media, consumer

1 Introduction

For this 28th edition of the Yearbook of Medical Informatics, the topic of "Artificial Intelligence (AI) in Health: New Opportunities, Challenges, and Practical Implications" is thought-provoking, especially when it comes to 're-imagining' the future for patients and consumers as AI technologies are increasingly introduced into our daily lives.

Over the past years, our ability to store large repositories of data has surpassed the ability to effectively and efficiently develop actionable knowledge from these sources.

For example, cloud artificial intelligence and machine learning platform services, known collectively as AI Platforms as a Service (PaaS), are placed at the peak of the Gartner hype curve in 2018 [1]. Due to the opportunity of having access to large quantities of data that were previously unavailable, and the technical challenge of not being able to deliver real-time actionable knowledge from these sources, many researchers have worked on enhancing machine learning algorithms to extract meaning from these sources. As a result, many of the AI applications we are witnessing today are reliant on having access to large repositories of

data. Success of these data-driven approaches varies across disciplines and depends on the quality and quantity of the data available, the specificity of the task, the appropriate choice of algorithms, the rigour in the execution, as well as the domain expertise available to guide the analysis and interpretation.

In health, recent AI developments that are showing promising results are data-driven approaches, specifically for clinician-facing applications such as image analysis and interpretation in radiology [2, 3]. In the world of patients and consumers, recent AI applications have also taken a data-driven approach. Social

media platforms, including online health communities, have become popular sources for individuals to connect and exchange support. Due to the relative ease to access publicly-available data, many researchers have tapped into mining social media as a way to explore how AI can be applied to get a better understanding of patient and consumer experiences. As a result, a majority of recent studies reporting AI approaches for patients and consumers focuses on secondary analyses of social media data [4]. While social media could be a good source to understand how individuals cope with and manage their conditions, they also present high risks due to widespread dissemination of poor-quality or incorrect information. As a result, researchers have proposed various data-driven approaches to analyse patients' online behaviours and address the problems they experience online, such as detecting disclosure of personal health information on Twitter [5] and determining which online health forum threads require moderator assistance [6].

However, these data-driven approaches, regardless of whether they are focused on clinicians, consumers, or patients, represent a narrow focus of AI [7]. In this paper, we examine how AI approaches are currently used for patients and consumers, present papers that are representative in the year 2018, and highlight untapped opportunities for research in AI for patients and consumers.

2 Methodology

2.1 Search Strategy

We used PubMed to conduct our search, capturing papers relevant to consumer health informatics and artificial intelligence published in the year 2018. The search strategy was based on the PICO framework, P-Population/Problem, I-Intervention, C-Comparison, O-Outcome, where 'Problem' refers to the various digital environments consumers and patients participate in, *e.g.*, social media, online health communities; "Intervention" comprises of various AI methods and technologies; and "Outcome" outlines the impact or resulting effects of participatory health, *i.e.*, patient-centred initiatives to empower individ-

uals in their health decisions and behaviours [4]. A "comparison" intervention was not included as it is not relevant in this review.

We started with a search query adopted from previous work [2, 4]. Step by step, we refined the query to include keywords related to digital/social media (41 keywords), artificial intelligence (52 keywords), and participatory health (24 keywords). MeSH terms and the syntax "[All Fields]" were used wherever possible to ensure our search strategy was comprehensive. The final search query is listed below:

((2018[DP] NOT pubstatusaheadofprint) NOT Bibliography[pt] NOT Comment[pt] NOT Editorial[pt] NOT Letter[pt] NOT News[pt] NOT Case Reports[pt] NOT Published Erratum[pt] NOT Historical Article[pt] NOT legislation[pt] NOT ("review"[pt] OR "review literature as topic"[MeSH] OR "literature review"[All Fields]))

erment” [All Fields] OR “citizen health” [All Fields] OR “citizen engagement” [All Fields] OR “citizen empowerment” [All Fields] OR “participative medicine” [All Fields] OR “personalized medicine” [All Fields] OR “precision medicine” [All Fields] OR “predictive medicine” [All Fields] OR “preventive medicine” [All Fields] OR “disease management” [All Fields])

2.2 Bibliometrics Analyses

To understand the state of the literature, we applied various bibliometrics tools onto the original set of articles returned from the search query. The “Bibliometrix” package from R [8] was used on the retrieved articles to report frequency of keywords used by

authors, and a topic dendrogram to cluster keywords and examine whether these clusters follow a hierarchical structure.

3 Results

3.1 State of the Literature

Ninety-nine articles were returned from the search query. Figure 1 reports the frequency of the 50 most common keywords used by authors in these retrieved articles. The five most frequent keywords are (from most frequent to least frequent): precision medicine, social media, big data, infodemiology, and machine learning, illustrating the current focus on data-driven approaches to AI for patients and consumers.

Figure 2 illustrates a dendrogram applied to the 99 retrieved articles to explore whether keywords used by authors tended to cluster in groups, and whether these clusters follow a hierarchical structure. Three small clusters emerged, illustrating the keywords that were commonly used together by authors when describing AI approaches for patients and consumers. For example: “machine learning” and “precision” in cluster 1; “infodemiology”, “mortality”, and “outcome” in cluster 2; and “forensic DNA phenotyping” and “DNA methylation” in cluster 3.

We did not observe a clear hierarchical structure amongst these clusters but “digital health” emerged as a unique term associated at the root of the tree. Furthermore, there is a list of keywords near the centre of the dendrogram that do not seem discriminant

Fig. 1 Frequency of authors' keywords in the 99 retrieved articles

Fig. 2 Topic dendrogram of author's keywords throughout the 99 retrieved articles.

enough to form a cluster (e.g., natural language processing, big data, depression, twitter, internet, text mining, etc.). The inability to form clusters amongst these keywords may suggest that although there is research activity in each of these individual areas, different authors used different approaches and there is not yet a body of work that combines these concepts, methods, or techniques when authors describe their work in the literature.

3.2 Best Paper Selection

The 99 retrieved articles were then screened by section editors, which resulted in 14 articles considered for best paper selection. Elements that were considered in the screening decision include: 1) level of relevance

regarding the 2019 yearbook topic “Artificial Intelligence in Health: New Opportunities, Challenges, and Practical Implications”; 2) whether the AI application was focused only on patients and consumers; 3) nature of the healthcare problem addressed; and 4) level of innovative approach.

The selected 14 articles were then presented to a panel of international experts for full paper review and scoring according to the IMIA Yearbook best paper selection process. The three papers that received the highest scores were then discussed in a consensus meeting, and it was agreed upon that they were representative papers on artificial intelligence in health for patients and consumers for the year 2018.

The final three best papers selected after peer review process are listed in Table 1.

These papers shared a common methodology of using data-driven algorithms (such as text mining, topic modelling, or Latent Dirichlet allocation modelling), combined with insight-led approaches (e.g. visualisation, qualitative analysis, or manual review), to uncover patient and consumer experiences of health and illnesses in online communities.

For example, Abdellaoui *et al.*, [9] outlined a methodology to detect medication non-compliance behaviours amongst people on antidepressant and antipsychotic medications by modelling the way dosage variation and treatment interruption behaviours were discussed online. Jones *et al.*, [10] demonstrated it was possible to uncover the hidden, less obvious aspects of breast cancer management and recovery in online discussion forums, including aspects that are not easily ascertainable

Table 1 Best paper selection of articles for the IMIA Yearbook of Medical Informatics 2019 in the section 'Education and Consumer Health Informatics'. The articles are listed in alphabetical order of the first author's surname.

in patient clinics (e.g., side effects while in remission, financial challenges experienced by cancer survivors over time). Similarly, Park *et al.*, [11] identified subtle differences in the types of concerns expressed online by individuals experiencing different mental health conditions (e.g., people with depression often discussed events associated with changes in mood whereas discussion topics amongst people with anxiety or post-traumatic stress disorder clustered around treatment- and medication-related issues).

4 Conclusions

Despite the attention and expectations given to artificial intelligence (AI), we did not find eligible articles published in 2018 that reported AI applications designed specifically for patients or consumers, nor literature that elicited patient and consumer input on AI. Currently, the most common use of AI for patients and consumers lies in secondary analysis of social media data (e.g., online discussion forums). In particular, the three 2018 best papers share a common methodology of using data-driven algorithms, combined with insight-led approaches, to uncover patient and consumer experiences in online communities.

Currently, there is a lack of direction and evidence on how AI would *actually* benefit patients and consumers. Perhaps instead of focusing on data and algorithms, researchers should engage with patients and consumers *early* in the AI research agenda to ensure we are indeed

asking the right questions, and that important use cases and critical contexts are identified together *with* patients and consumers. Without a clear understanding on why patients and consumers need AI in the first place, how AI could support individuals with their healthcare needs, and what are the capabilities and limitations of AI, it is difficult to imagine the kinds of AI applications that would have meaningful and sustainable impact on individuals' daily lives.

Artificial Intelligence in 2018 may not yet be at the state that meets the expectations of patients and consumers. However, this presents a number of untapped opportunities for research. While many have already made way in using data-driven and machine learning approaches in health, perhaps the challenge of AI for patients and consumers lies in how people will interact with the technology (i.e. human-computer interaction) [4]. For patients and consumers to truly benefit from AI, the design of the technology may need to be embedded deeply in their environment or perhaps even invisibly in their daily routine [4]. For example, with the rise of voice-only or voice-first interfaces, one could explore whether conversational agents have a role to support patients and consumers with their daily tasks [12]. In addition, real-life decision support for patients and consumers remains an open opportunity provided the right problem, use case, and interaction mode are identified. To conclude, we leave readers with the words of Heht [13]: "The public's view of artificial intelligence might not be accurate, but that doesn't mean researchers can ignore it".

Detection of Cases of Noncompliance to Drug Treatment in Patient Forum Posts: Topic Model Approach

J Med Internet Res 2018;20(3):e85

Non-compliance (or non-adherence) to long-term treatment is a worldwide problem detrimental to the overall effectiveness of the health system. Social media holds a lot of promise in improving communication and patient engagement. The example of benfluorex illustrates how social media could be valuable sources for experts. Methods to identify messages with adverse events mentions have been developed and it has been showed that social media may even impact treatment adherence. The objective of this study was to evaluate a topic model approach to detect patient non-compliant behaviours (dose change and treatment cessation) associated with antidepressant drug (escitalopram) and antipsychotic drug (aripiprazole) in online forums. Authors implemented a probabilistic topic model to identify the topics that occurred in a corpus of messages mentioning these drugs, posted from 2004 to 2013 on three of the most popular French forums. Around 6% (154/2691) of online posts were detected on escitalopram non-compliance and 7% (122/1778) on aripiprazole. The topic models approach detected cases of non-compliance behaviours with average recall and precision scores of 98.5% (272/276) and 32.6% (272/844), respectively. Authors concluded topic modelling was a valuable sensitive method to detect non-compliance. However, it lacks specificity and manual review was required to distinguish between true and false positives in each dataset. They suggested that syntactic and semantic methods could be

developed to recognize the experience, the temporal features, and the object concerned by the action in the sentences.

Novel Approach to Cluster Patient-Generated Data Into Actionable Topics: Case Study of a Web-Based Breast Cancer Forum

JMIR Med Inform 2018;6(4):e45

Despite the proliferation of social media use, such as blogs and forums, little is known about the scope and quality of information shared, or the purposes that social media sites serve for consumer decisional and support needs. This study explores approaches for analysing the free-text social media data to discover hidden, less obvious, aspects of health consumers' lives and extract potential valuable information on managing health and well being beyond the context of health care. This was applied to breast cancer management and recovery in five online breast cancer forums (mainly breastcancer.org community). Natural language processing and statistical modelling approach were used to cluster >4 million postings into manageable topics. Topic modelling (cluster of words that frequently occur together) was performed with the machine learning language toolkit open source tool. It was followed by multiple linear regression analysis to detect highly correlated topics among the different website forums. Quantitative content analysis of the forums resulted in 20 categories of user discussion. Topic model organized posts into 30 topics which were grouped into four distinct clusters of highly correlated computationally modelled topics. These clusters were labelled "symptoms and diagnosis", "treatment", "financial", "friends and family". Multiple regression analysis was performed to identify the most significant topics discussed among the forum participants. They were arranged in a descending order based on the Akaike information criterion value: 1) lingering side effects while in remission, 2) chemotherapy side effects and change of treatment, 3) radiation and side effects, 4) genetic risk

and testing, 5) support from caregiver and medical team for long term recovery, and 6) looking for support from people in similar circumstances.

Examining Thematic Similarity, Difference, and Membership in Three Online Mental Health Communities from Reddit: A Text Mining and Visualization Approach

Comput Human Behav 2018 Jan;78:98-112

Studies have consistently shown individuals can gain positive effects from interacting with other individuals in similar circumstances. Online interactions have been shown to improve depression, anxiety, stress, and negative mood, as well as to facilitate coping and empowerment. Moreover, members of online health communities consistently emphasize the benefits of participation with respect to their treatment decisions, symptom management, clinical management, and outcomes. In this study, authors examine the nature of online discussion (main themes expressed in the communities) and compare issues (thematic overlap, similarity and differences among the communities) pertaining to three mental health conditions: anxiety, depression, and post-traumatic stress disorder (PTSD). The corpus was based on Reddit (<http://www.reddit.com>), a popular social networking, online gathering, and news exchanging platform. Between the months of Oct 2015 to Dec 2015, a total of 7,410 posts and 132,599 associated comments made by 41,967 unique members were downloaded. Discussion themes were identified using knowledge resources like Unified Medical Language System or clusters analysis. Similarity among clusters in the network visualization used Louvain modularity algorithm. For each of the three main themes (anxiety, depression, and PTSD), 15 clusters had been generated. Using r/Anxiety subreddit discussion content, clusters including "social anxiety", "medication", "school", "panic attack", and "therapy/therapist" contained terms and labels which clearly differentiated the clusters from one another. A few clusters, such as "positive emotion" and "gratitude" shared terms. For the r/Depression subreddit, clusters including "birthday", "school",

“sleep”, “work”, and “gratitude” were clearly differentiated from one another. Clusters such as “talking to friends” and “friends and family” shared identical or semantically similar terms. For the r/PTSD subreddit, many clusters including “trauma therapy”, “work”, “sleep”, “trauma trigger”, “EMDR therapy”, “nightmare”, “animal”, “research”, were clearly distinguishable. A few clusters, such

as “sleep” and “nightmare” shared similar terms but also had distinctive and non-overlapping terms. Venn diagrams were built to summarize and highlight common themes: “school” and “social related” between Anxiety Disorder and Depression, “living with” between Anxiety Disorder and PTSD. The global intersection between the three communities shared overlapping concerns

and discussion patterns such as: “gratitude”, “sleep”, “work” and “positive emotion”. However, Depression clusters focused on self-expressed concerns (e.g., events associated with depressed moods), whereas Anxiety Disorders and Post-Traumatic Stress Disorder clusters focused around treatment- and medication-related issues.
